

Appendix B. Social event data experiments

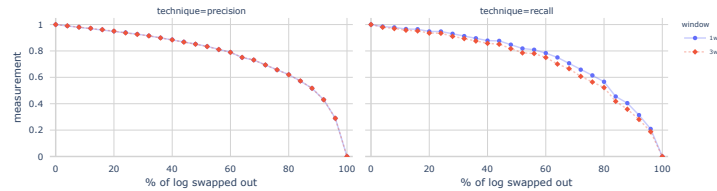

This document contains additional experiments on social event data. Social network event logs from Twitter misinformation campaigns presented by [1] were investigated. From [1], three logs: Brazil (Figure 1a), Honduras (Figure 1b), and UAE (Figure 1c) were selected.

(a) Social interactions from Brazil log using windows of 1 and 3.

(b) Social interactions from Honduras using windows of 1 and 3.

(c) Social interactions from UAE using windows of 1 and 3.

Figure 1: Results for measures across event logs and models discovered from these event logs using different windows and different proportions of replaced traces.

The process of replacing traces in the log was applied to evaluate the monotonicity of the conformane checking technique. These logs by their nature consist mostly of unique variants. Across all three event logs, the results demonstrate

clear monotonicity in the precision measurements and a general monotonic trend in the recall measurements.
